Abstract—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders between two groups of nurses working in different departments of a tertiary care hospital. The study included 100 nurses from the medical-surgical department and 100 nurses from the intensive care unit. Data were collected through a self-administered questionnaire. Results showed that the prevalence of musculoskeletal disorders was higher among nurses in the intensive care unit compared to those in the medical-surgical department. This finding suggests that interventions aimed at reducing musculoskeletal risk factors should be tailored to the specific work environments.
